Summary

This study was conducted because of influence of prebiotics (alphamune) and symbiotic (biomin) on histometrical development of small intestine and lymphatic tissue of caecal tonsil have been not reported on broiler chicken. In this study, different parts of small intestine and caecal tonsil, which is a major area of gut associated lymphatic tissue (GALT) in chicken were selected. One hundred and twenty-five 1-day-old broiler chicks were divided into 3 groups: 1) Control group which were fed only by basal diet, 2) Alphamune group which were fed basal diet supplemented with prebiotic (0.5 kg/ton alphamune), and 3) Biomin group, fed basal diet supplemented with symbiotic (1 kg/ton biomin). At the end of 42 days, 15 chicks (5 chicks from each group) were selected for histomorphometrical study. The samples were taken from different parts of small intestine (duodenum, jejunum and ileum) and caecal tonsils and fixed in 10% formalin. The 5-6 µ sections were made by paraffin embedding method and stained by H&E. The results showed that although alphamune and biomin have a significant improvement on histomorphological structure of small intestine and its associate lymphatic tissue. Villous height and thickness, the number of goblet cells, number and depth of intestinal crypt, density and area of aggregated lymphatic tissue were increased more significantly in biomin group (P<0.05). The knowledge obtained from this study showed that alphamune and biomin are considerable feed additives instead of antibiotic for improvement of histomorphological structure of small intestine and its associate lymphatic tissue.

Key words: Prebiotic, Symbiotic, Histomorphometrical, Broiler chicken

Introduction

In the poultry industry, antibiotics are used worldwide to prevent poultry pathogens and disease so as to improve meat and egg production. However, the use of dietary antibiotics resulted in common problems as to improve meat and egg production. However, the use of dietary antibiotics resulted in common problems such as development of drug-resistant bacteria (Sorum and Sunder, 2001), drug residues in the body of the birds (Burgat, 1999), and imbalance of normal micro flora (Andremont, 2000). As a consequence, it has become necessary to develop alternatives using either beneficial microorganisms or nondigestible ingredients that enhance microbial growth. A probiotic is defined as a live microbial feed supplement that beneficially affects the host animal by improving its microbial intestinal balance (Fuller, 1989). On the other hand, a prebiotic is defined as nondigestible food ingredient that beneficially affects the host, selectively stimulating the growth or activity, or both, of one or a limited number of bacteria in the colon (Gibson and Roberfroi, 1995). Lactobacilli and enterococci are among the wide variety of microbial species that have been used extensively as probiotics (Patterson and Burkholder, 2003). After feeding of probiotics, improvements in growth performance and feed efficiency have been reported in broiler chickens (Cavazzoni et al., 1998; Jin et al., 1998; Zulkifli et al., 2000; Kabir et al., 2004; Mountzouris et al., 2007; Samli et al., 2007).

Recently, Chichlowski et al. (2007) reported that a probiotic containing Lactobacilli bifidobacterium thermophilum and Enterococcus faecium increased the jejunal villous height and decreased the villous crypt depth compared with salinomycin and control. Moreover, shorter and thinner villi were associated with toxins (Yason et al., 1987; Awad et al., 2006). In contrast, longer villi were found in the ileum of adult male layers with slight improvement in feed efficiency after dietary addition of Bacillus subtilis var. natto (Samanya and Yamauchi, 2002) and in broilers after addition of E. faecium (Samli et al., 2007) or Eubacterium sp. (Awad et al., 2006). Insulin and fructooligosaccharides are probably the most commonly used prebiotics; several typical probiotics contain either of these oligosaccharides, thereby comprising a symbiotic. A way of potentiating the efficacy of probiotic preparations may be the combination of both probiotics and prebiotics as symbiotics. The combination of a probiotic and probiotic in 1 product has been shown to confer benefits beyond those of either on its own (Gallaher and Khil, 1999). When evaluating the efficacy of potential antibiotic alternatives on bird health and productivity, it is also important to analyse the...
competence of the immune cells in the gut associated lymphoid tissue (GALT), because it is routinely involved in the surveillance of colonizing microbes as well as in interacting with the ingested feed antigens. The effects of a symbiotic and a probiotic on the development of intestinal histomorphology in association to their improvement on GALT in broilers chick is still not completely clear. Therefore, the present study was conducted to investigate the effects of a symbiotic (biomin mabo) and a probiotic (alphamune) on broiler histomorphometrical of developing small intestinal mucosa and caecal tonsil (CT) lymphoid tissue, which is a major GALT in poultry.

Materials and Methods

One hundred and twenty-five 1-day-old broiler chicks were obtained from commercial hatchery. The birds were randomly divided into 3 groups: 1) Control group which were fed only by basal diet, 2) Alphamune group which were fed basal diet supplemented with prebiotic (0.5 kg/ton alphamune which is a yeast extract antibiotic alternative, mannan-oligosaccharide), and 3) Biomin group, which were fed basal diet supplemented with symbiotic (1 kg/ton biomin which is a combination of the probiotic strain Enterococcus faecium (DSM 3530), a prebiotic (derived from chicory), and immune-modulating substances (derived from sea algae).

At the end of 42 days, 15 chicks (5 chicks from each group) were selected for histomorphometrical study. The samples were taken from different parts of small intestine (duodenum, jejunum and ileum) and caecal tonsil and were fixed in 10% formalin. The 5-6 µ sections were made by paraffin embedding method and stained by H&E. The micrometrical analysis was done using Dino-Lite Digital Microscope, Digital Dino-Lite Eye-Piece and Dino-Capture 1 software on microphotographs.

Statistical analysis

One way analysis of variance (ANOVA) was performed for data analyses. Differences between groups were considered to be significant in P<0.05.

Results

The histomorphometrical measurement results of different parts of small intestine and lymphoid tissue of caecal tonsil are shown in Tables 1 and 2.

Caecal tonsil

A paired caeca were seen in large intestine in which a paired caecal tonsil was situated in the basal part of each one. They were recognized easily from other parts by more wall thickness and diameter. Caecal tonsil mucosa has a different structure; a part of it which contains accumulated mass of lymphoid tissue (tonsil) avoids villous but instead has thick and high folds containing nodular units, so that this part has a thicker wall than other parts. The facing wall which is without tonsil is covered by long villous, similar to those in small intestine and its thickness is less than the tonsil part (Figs. 3 and 4).

The caecal tonsil lumen is almost closed completely by villous and mucosa-submucosa folds of nodular units. Nodular units are tonsil like structures formed by mucosal-submucosal folds and surrounded by a delicate layer of smooth muscle branching out of an inner circular muscle layer and muscularis mucosa. Surface epithelium has made a deep crypt into the nodular unit, mostly covered by short villous. Diffuse and nodular lymphatic tissue fills the lamina propria.

A more interesting finding is increasing and improvement of density and area of aggregated lymphoid tissue and the relationship of lymphoid area of CT to the entire CT circumference in biomin and alphamune groups compared to control group (P<0.05), which caused the diameters and wall thickness of CT, height and thickness of nodular unit to increase (Table 2). The biomin has more significant improvement on lymphatic tissue of caecal tonsil compared to alphamune groups. The diffuse lymphatic tissue and lymph nodules in lamina propria-submucosa were also increased in different parts of caecal tonsil.

Discussion

The results of the present study showed that although the alphamune and biomin improved the development of histomorphological structure of small intestine and caecal tonsil lymphoid tissue of broiler chicken, the biomin has more significant improvement which is in agreement with Awad et al. (2006). The improvement was more effective on duodenum than other parts of small intestine. Increasing the villous height suggests an increased surface area capable of greater absorption of available nutrients (Caspary, 1992). The villous crypt is considered as the villous factory and deeper crypts indicate fast tissue turnover to permit renewal of the villous as needed in response to normal sloughing or inflammation from pathogens or their toxins and high demands for tissue (Yason et al., 1987) and Anonymous (1999). The intestinal epithelial cells originating in the crypt migrate along the villous surface upward to the villous tip and are extruded into the intestinal lumen within 48 to 96 h (Imoni and Bird, 1966; Potten, 1998). A shortening of the villi and deeper crypts may lead to poor nutrient absorption, increased secretion in the gastrointestinal tract, and lower performance (Xu et al., 2003). In contrast, increases in the villous height and crypt depth ratio is directly correlated with increased epithelial cell turnover (Fan et al., 1997) and longer villi are associated with activated cell mitosis (Samanya and Yamauchi, 2002). Longer villi were found in the ileum of chicks and turkeys treated with Lactobacillus reuteri (Dunham et al., 1993) and in the ileum of adult male layers with slight improvement in feed efficiency after dietary addition of Bacillus subtilis var. natto (Samanya and Yamauchi, 2002). Feeding of probiotics has been shown to induce gut epithelial cell proliferation in rats (Ichikawa et al., 1999). In addition, longer villi were induced by dietary amylose (Ritz et al., 1995). The concentrations of amylose in broiler intestine were increased after supplementation of diet with either a single strain of Lactobacillus acidophilus or a mixture of Lactobacillus strains (Jin et al., 2000). Awad et al. (2006) reported that the crypt depth was not affected by dietary treatment (alphamune and biomin) and symbiotic and probiotic supplementations increased villous height; crypt depth ratio significantly and the villous height numerically compared with the control. However, the villous height and crypt depth were increased significantly in the present study, particularly in duodenum. It is assumed that an increased villous height is paralleled by an increased digestive and absorptive function of the intestine due to increased absorptive surface area, expression of brush border enzymes, and nutrient transport systems (Pluske et al., 1996). It is understood that greater villous height is an indicator that the function of intestinal villi is activated (Langhout et al., 1999; Yasar and Forbes, 1999; Shamoto and Yamauchi, 2000). This fact suggests that the villous function is activated after feeding of dietary symbiotic or probiotic. Moreover, increased passive absorption of glucose and proline was reported in broiler chickens fed a probiotic containing Lactobacilli, B. thermophilum, and E. faecium (Chichlowski et al., 2007). The density and area of aggregated lymphoid tissue was improved significantly also in biomin group, which caused an increase in the diameters and wall thickness of CT, height and thickness of nodular unit. Spring et al. (2000) reported that although mannan oligosaccharides (MOS) have been used as the prebiotics they do not selectively enrich for beneficial bacterial populations. Instead, they are thought to act by binding and removing pathogens from the intestinal tract and stimulation of the immune system. Other studies have demonstrated positive effects of biomin on immune system effectiveness and newly described prebiotics can modulate various properties of the immune system, including those of the gut-associated lymphoid tissues (GALT). Changes in the intestinal micro flora that occur with the consumption of prebiotic fibres may potentially mediate immune changes via the direct contact of lactic acid bacteria or bacterial products (cell wall or cytoplasmic components) with immune cells in the intestine; the production of short-chain fatty acids from fiber fermentation; or by changes in mucin production (Schley and Field, 2000). However, Janardhana et al. (2009) reported that the addition of prebiotics to diet resulted in a significant reduction in the...
proportion of B cells and in mitogen responsiveness of lymphocytes in caecal tonsil. The prebiotic maintain a beneficial microbial population by competitive exclusion and antagonism (Fuller, 1989). Alphamune, a yeast extract antibiotic alternative, has been shown to stimulate the immune system increased BW in pigs, and reduce Salmonella colonization in chickens (Solis de los Santos et al., 2007). Hosseini (2011) reported that Saccharomyces cerevisiae has significant effects on visceral and immune organs. Lactobacilli and enterococci are among the wide variety of microbial species that have been used extensively as probiotic enhanced concentrations of circulating immunoglobulin A (IgA), (Kaila et al., 1992; Akinleye, 2000). Inhibition of pathogens by the intestinal microbiota has been called bacterial antagonism, bacterial interference, barrier effect, colonization resistance, and competitive exclusion. Mechanisms by which the indigenous intestinal bacteria inhibit pathogens include competition for colonization sites, competition for nutrients, production of toxic compounds, or stimulation of the immune system (Patterson and Burkholler, 2003). These findings emphasize the need for the analyses of the gut immune function following treatment with novel feed additives. The knowledge obtained from such study may aid in understanding the mechanisms underlying the immune competence of the birds, which needs consideration when selecting and optimizing new feed additives instead of antibiotics for poultry production. Although further work is needed to better define the changes, mechanisms for immunomodulation, and the ultimate impact on immune health, there is convincing preliminary data to suggest that the consumption of prebiotics can modulate immune parameters in GALT and secondary lymphoid tissues.

Alphamune and biomin treatment showed that biomin significantly improved and increased the small intestine (more significantly in duodenum) histomorphological structure and caecal tonsil lymphatic tissue. Furthermore, the dietary supplementation resulted in an increase in the villous height and crypt depth of intestinal mucosa of broilers, and increasing the lymphoid tissue in caecal tonsil might be a promising alternative for antibiotic growth promoters as pressure to eliminate antibiotic growth promoters in animal feed increases. The symbiotic offers a good alternative to improve poultry production.
